A surface modification process changes the properties of the surface, but the substrate material is still present on the surface. One of such processes is physical vapor deposition (PVD) processes that are atomistic deposition processes in which material is vaporized from a solid or liquid source in the form of atoms or molecules and transported in the form of a vapor through a vacuum or low pressure gaseous (or plasma) environment to the substrate, where it condenses.

Vacuum deposition (or vacuum evaporation), is a physical vapor deposition (PVD) process in which the atoms or the molecules from a thermal vaporization source reach the substrate without collisions with residual gas molecules in the deposition chamber. This type of PVD process requires a relatively good vacuum.

Physical vapor deposition, sometimes called physical vapor transport, describes a variety of vacuum deposition methods which can be used to produce thin films and coatings. PVD is characterized by a process in which the material goes from a condensed phase to a vapor phase and then back to a thin film condensed phase. The most common PVD processes are sputtering and evaporation. PVD is used in the manufacture of items which require thin films for mechanical, optical, chemical or electronic funct

It is by far the most f30 Handbook of Chemical Vapor Deposition important area of CVD and is estimated to comprise three-quarters of all CVD production. In this book, the CVD applications are classified by product functions such as electrical, opto-electrical, optical, mechanical and chemical.

In contrast, physical vapor deposition (PVD) techniques, such as sputtering or evaporation, generally require a line-of-sight between the surface to be coated and the source. Another advantage of CVD is that, in addition to the wide variety of materials that can be deposited, they can be deposited with very high purity.
